What can be improved

Last week I showed some results of bagging and boosting with 16-50-26 nets. The testing error decreases from 11% (one hypothesis) to 5% (simple boosting/AdaBoost.M1). Errors of bagging are higher.

According to Schwenk and Bengio's Boosting Neural Networks, the errors should be 7% (one hypothesis) and below 2% (AdaBoost.M2).

I should improve

• the base architecture and

• the aggregation algorithm.
More Layers

Stochastic Gradient Descent

Randomly select a sample according to distribution $D$, for each feed-forward / back-propagation.

Schwenk claimed this is better than conjugate-gradient, since there are so many examples.

I tested this method with different learning rates.
AdaBoost
Freund and Schapire. Experiments with a New Boosting Algorithm.

- We have a “weak” learning algorithm; want to make it “strong”
- Boost it! Combine many “weak” hypotheses
- Different from bagging: emphasize on “bad” samples; combine hypotheses with different weights

AdaBoost.M1
We have $D_t(i)$ as the weight for $i^{th}$ sample $(x_i, y_i)$ at iteration $t$

- generate $h_t$ according to samples and $D_t(i)$
- error is $\epsilon_t = \sum_i D_t(i) \cdot (h_t(x_i) \neq y_i)$
- $\beta_t = \epsilon_t^{-1} - 1$; $h_t$ has weight $\log \beta_t$.
- Update $D$ as $D_{t+1}(i) \propto D_t(i) \beta_t^{h_t(x_i) \neq y_i}$

We need $\epsilon_t < 0.5$. For two-class problem, it is easy; however, ...

AdaBoost.M2 for multi-class problems
We have $D_t(i, y)$ as the weight for $x_i$ and $y \neq y_i$ at iteration $t$

- generate $h_t$ according to samples and $D_t(i, y)$
- pseudo-loss is $\epsilon_t = \frac{1}{2} \sum_{i,y} D_t(i) \cdot (1 - h_t(x_i, y_i) + h_t(x_i, y))$
- $\beta_t = \epsilon_t^{-1} - 1$; $h_t$ has weight $\log \beta_t$.
- Update $D$ as $D_{t+1}(i, y) \propto D_t(i, y) \beta_t^{\frac{1}{2}(1 - h_t(x_i, y_i) + h_t(x_i, y))}$

Now boosting algorithm has more communication with the “weak” one. $h_t(i, y)$ is the likelihood that $x_i$ belongs to class $y$.

Results with Bagging

Bagging still does a worse job.
